Introduction: Biotechnologies are the contemporary medical technologies that interfere in vital processes, involving social relations that put in circulation new meanings about life and about optimizing the future. Promises and prospects arising from the biotechnology field occupy a place of excellence and centrality, guiding both the wishes of subjects and perspectives of professionals enhance life. We can mention as an example the use of stem cells for handicap's persons aiming to recover their motor functions. It is possible to say that the biotechnologies have gained an increasing space in physical deficiency treatments. Objective: To discuss Biotechnologies discourses and its interface with physically disabled's stem cells treatments. Methodology: Experience report of theoretical productions coming from the Biotechnology research project and care practices - speeches of teachers and academics. Discussion: By creating different ways of body's understanding, biotechnologies make its existence possible and enhance the notion that one can act on oneself and correct aspects that are outside the imposed rules. The stem cells will be reassigning important cellular functions in the rehabilitation of body's movements. These are health practices that reframe this handicap body in its most intimate and essential aspects. This aspect highlights the emergence of biotechnologies that have caused cultural and political implications on the perception of disability. Final considerations: The making of oneself through biotechnologies is at life's service that must be consumed daily. Regarding disability, biotechnologies aim recovering the physical conditions "taken" as normal. Biotechnologies are not imposed, they are strategies built under certain conditions, which are constantly changing. We can say that they also function as forms of government, as they control the possibility of intervention and correction of life, making it an artifact that must be modified. It is the possibility of manipulating this handicap body that, from Biotechnologies, is able to be restored.
